### Training Set

Part-of-speech taggers use a training set where every word is hand-annotated (Penn Treebank and CoNLL 2008).

Index	Word	Hand annotation	Index	Word	Hand annotation

# Part-of-Speech Tagging with Linear Classifiers

Linear classifiers are efficient devices to carry out part-of-speech tagging:

- The lexical values are the input data to the tagger.
- The parts of speech are assigned from left to right by the tagger.

Given the feature vector:  $(w_{i-2}, w_{i-1}, w_i, w_{i+1}, w_{i+2}, t_{i-2}, t_{i-1})$ , the classifier will predict the part-of-speech tag  $t_i$  at index i.

#### POS Annotation with the Noisy Channel Model

Modeling the problem:

$$t_1, t_2, t_3, ..., t_n \rightarrow \text{noisy channel} \rightarrow w_1, w_2, w_3, ..., w_n.$$

The optimal part of speech sequence is

$$\hat{T} = \underset{t_1, t_2, t_3, ..., t_n}{\arg \max} P(t_1, t_2, t_3, ..., t_n | w_1, w_2, w_3, ..., w_n),$$

The Bayes' rule on conditional probabilities:

$$P(A|B)P(B) = P(B|A)P(A)$$
.

$$\hat{T} = \arg\max_{T} P(T)P(W|T).$$

P(T) and P(W|T) are simplified and estimated on hand-annotation corpora, the "gold standard".

EDAN20 Language Technology http://cs.lth.se/edan20/

#### The First Term: N-Gram Approximation

$$P(T) = P(t_1, t_2, t_3, ..., t_n) \approx P(t_1)P(t_2|t_1)\prod_{i=3}^n P(t_i|t_{i-2}, t_{i-1}).$$

If we use a start-of-sentence delimiter  $\langle s \rangle$ , the two first terms of the product,  $P(t_1)P(t_2|t_1)$ , are rewritten as  $P(\langle s \rangle)P(t_1|\langle s \rangle)P(t_2|\langle s \rangle,t_1)$ , where  $P(\langle s \rangle)=1$ .

We estimate the probabilities with the maximum likelihood,  $P_{MIF}$ :

$$P_{MLE}(t_i|t_{i-2},t_{i-1}) = \frac{C(t_{i-2},t_{i-1},t_i)}{C(t_{i-2},t_{i-1})}.$$

#### Sparse Data

If  $N_p$  is the number of the different parts-of-speech tags, there are  $N_p \times N_p \times N_p$  values to estimate. If data is missing, we can back off to bigrams:

$$P(T) = P(t_1, t_2, t_3, ..., t_n) \approx P(t_1) \prod_{i=2}^{n} P(t_i | t_{i-1}).$$

Or to unigrams:

$$P(T) = P(t_1, t_2, t_3, ..., t_n) \approx \prod_{i=1}^{n} P(t_i).$$

And finally, we can combine linearly these approximations:

$$P_{LinearInter}(t_i|t_{i-2}t_{i-1}) = \lambda_1 P(t_i|t_{i-2}t_{i-1}) + \lambda_2 P(t_i|t_{i-1}) + \lambda_3$$
 with  $\lambda_1 + \lambda_2 + \lambda_3 = 1$ , for example,  $\lambda_1 = 0.6$ ,  $\lambda_2 = 0.3$ ,  $\lambda_3 = 0.1$ .

#### The Second Term

The complete word sequence knowing the part-of-speech sequence is usually approximated as:

$$P(W|T) = P(w_1, w_2, w_3, ..., w_n|t_1, t_2, t_3, ..., t_n) \approx \prod_{i=1}^n P(w_i|t_i).$$

Like the previous probabilities,  $P(w_i|t_i)$  is estimated from hand-annotated corpora using the maximum likelihood:

$$P_{MLE}(w_i|t_i) = \frac{C(w_i,t_i)}{C(t_i)}.$$

For  $N_w$  different words, there are  $N_p \times N_w$  values to obtain. But in this case, many of the estimates will be 0.

### The POS Tagging Equation

$$\hat{T} = \arg\max_{T} P(T)P(W|T).$$

Using a bigram approximation, we have:

$$\hat{T} = P(t_1) \prod_{i=2}^{n} P(t_i|t_{i-1}) \times \prod_{i=1}^{n} P(w_i|t_i).$$

With:

$$P_{\mathsf{MLE}}(t_i|t_{i-1}) = \frac{C(t_{i-1},t_i)}{C(t_{i-1})}$$

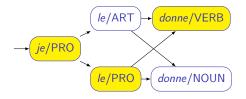

and

$$P_{\mathsf{MLE}}(w_i|t_i) = \frac{C(w_i,t_i)}{C(t_i)}.$$

#### An Example

Je le donne 'I give it'

- $P(pro|\emptyset) \times P(art|\emptyset, pro) \times P(verb|pro, art) \times P(je|pro) \times P(le|art) \times P(donne|verb)$
- **2**  $P(pro|\emptyset) \times P(art|\emptyset, pro) \times P(noun|pro, art) \times P(je|pro) \times P(le|art) \times P(donne|noun)$
- $P(pro|\emptyset) \times P(pro|\emptyset, pro) \times P(verb|pro, pro) \times P(je|pro) \times P(le|pro) \times P(donne|verb)$
- $P(pro|\emptyset) \times P(pro|\emptyset, pro) \times P(noun|pro, pro) \times P(je|pro) \times P(le|pro) \times P(donne|noun)$

## Viterbi (Informal)

Je le donne demain dans la matinée 'I give it tomorrow in the morning'

## Viterbi (Informal)

The term brought by the word *demain* has still the memory of the ambiguity of *donne*:  $P(adv|verb) \times P(demain|adv)$  and  $P(adv|noun) \times P(demain|adv)$ .

This is no longer the case with dans.

According to the noisy channel model and the bigram assumption, the term brought by the word dans is  $P(dans|prep) \times P(prep|adv)$ .

It does not show the ambiguity of le and donne.

The subsequent terms will ignore it as well.

We can discard the corresponding paths.

The optimal path does not contain nonoptimal subpaths.

### Trellis Representation

## Filling the Trellis

$i \setminus \delta$	$\delta_1$	$\delta_2$	$\delta_3$	$\delta_4$	$\delta_5$	$\delta_6$	$\delta_7$	$\delta_8$
PREP	0	1						
ADV	0	1						
PRO	0	// <sub>1</sub>						
VERB	0							
NOUN	0 //	/ > /						
ART	0	,						
<g>&gt;</g>	1.0	0	0	0	0	0	0	0
	<s></s>	Je	le	donne	demain	dans	la	matinée

To fill the  $\delta_3$  column, for each cell j, we compute

$$\max_{i} P(j|i) \times P(le|j) \times \delta_2(i).$$

The pronoun cell, for instance, is filled with

$$\max_{i} \ P(\mathsf{PRO}|i) \times P(\mathit{le}|\mathsf{PRO}) \times \delta_2(i).$$

## Worked Example in English

That round table might collapse

Looking up the words in a dictionary shows a lot of ambiguity: What is the part of speech of *That*? determiner? pronoun? relative pronoun?

Correct tags:

That/determiner round/adjective table/noun might/modal verb collapse/verb.

Using the Penn Treebank tagset:

That/DT round/JJ table/NN might/MD collapse/VB.

# Statistics from the Corpus

```
$ cut -f2,5 <corpus.txt | sort | uniq -c | grep " That\t"

## Viterbi: The Complete Algorithm

Steps	Operations
1. Initialization	$\delta_1(i) = \pi_i b_i(o_1), 1 \le i \le N_p$
	$\psi_1(i) = null$
2. Induction	$\delta_{t+1}(j) = b_j(o_{t+1})  imes \max_{1 \leq i \leq N_p} \delta_t(i) a_{ij}, 1 \leq j \leq N_p$ , and $1 \leq j \leq N_p$
	$t \le n-1$
	$\psi_{t+1}(j) = rg\max_{1 \leq i \leq N_p} \delta_t(i) a_{ij}$
3. Termination	$P*=\max_{1\leq i\leq N_p} \delta_n(i)$
	$s_n* = rg\max_{1 \leq i \leq N_p} \delta_n(i)$
	The optimal path sequence is given by the backtracking:
	$s_n^*, s_{n-1}^* = \psi_n(s_n^*), s_{n-2}^* = \psi_{n-2}(s_{n-1}^*), \dots$

### Supervised Learning: A Summary

Needs a manually annotated corpus called the **Gold Standard**The Gold Standard may contain errors (*errare humanum est*) that we ignore A classifier is trained on a part of the corpus, the **training set**, and evaluated on another part, the **test set**, where automatic annotation is compared with the "Gold Standard"

**N-fold cross validation** is used avoid the influence of a particular division Some algorithms may require additional optimization on a development set Classifiers can use statistical or symbolic methods
